

Overview

LLVM Extensions

Loop transformations with Polly, Clang & LLVM

- Improve support for loop transformations in Clang/LLVM
 - Add more transformations
 - Composable transformations
 - Interaction with parallelism
- Controllable using in-source #pragma annotations
 - e.g. #pragma clang loop transform sizes(32,16)
- Using Polly in the implementation
 - Code modifications become tree transformations
- Effort to add to the OpenMP 6.0 standard

Benefits and Results

- Separation of semantics and optimization
- Use case *dgemm*: Already reached 42% of theoretical peak performance with tiling, interchange and array packing.

SuRF / Autotuning

SuRF: Search Using Random Forests for autotuning search

- Asynchronous search method with manager-workers approach
- Random forest as a surrogate model to navigate the search space
- Bayesian methods for exploration and exploitation of the search history
- Interface for expressing wide range of problems, constraints and performance models (with xSDK4ECP)

Benefits and Results

- Finds high-performing parameter configurations in short wall-clock time
- Demonstrated effectiveness on superlu library and qmcpack application autotuning
- Scaled up to 64 worker nodes to reduce the search time significantly
- Interface allows to prune the search space
 - user defined constraints
 - performance models
 - other search methods

```

from autotune import TuningProblem
from autotune.space import Input
from autotune import Search

task_space = Spaces(Categorical("a", "b", "c", name="job"))
input_space = Spaces(Integer(10, name="N"))
output_space = Spaces(Float(0, inf, name="time"))

def objective(point):
    from math import exp
    return exp(-point["x"])

def analytical_model(point):
    return 1 + point["x"]

constraints = {"a": "a", "b": "b"}

problem = TuningProblem(task_space, input_space, output_space, objective, constraints,
                        analytical_models)

search_param_dict["method"] = "MLA"
search = Search(problem, search_param_dict)
search.run()
    
```

Pragma Autotuning

Benefits and Impact

- Employs autotuning to achieve performance portability (CPU and GPU) of compiler transformations and OpenMP
- Replace descriptive OpenMP pragmas with prescriptive ones
- Vary Clang loop transformation pragmas, profitable settings for compiler and loop level parameters
- **Improve application programmer productivity!**

```

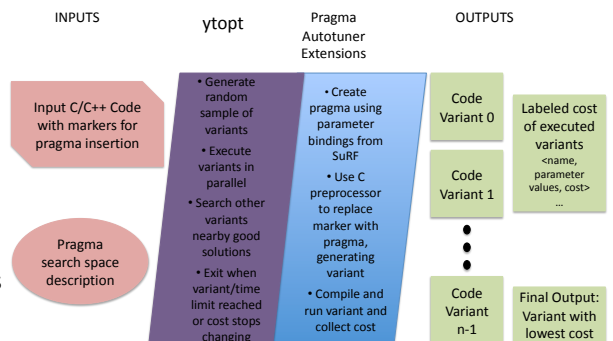

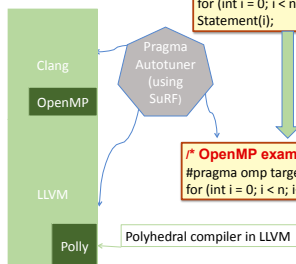

/* Polly example */
#pragma clang loop transform sizes(#P0,#P1)
for (int i = 0; i < n; i+=1) Statement(i);
    
```

```

/* OpenMP example */
#pragma omp parallel loop
for (int i = 0; i < n; i+=1)
Statement(i);
    
```

```

/* OpenMP example */
#pragma omp target distribute simd
for (int i = 0; i < n; i+=1) Statement(i);
    
```
